## TICK ANALYSIS DATA SHEET

Page of pages		Installation sample #		СНРРІ	M sample #	Date rec'd:	
Identified by:	Call-in date (I.E	o.) <b>to</b> :	by:	Tested by:	Call-in date (tests)	to:	by:

TICK IDENTIFICATION	Sex & Stage			Engorgement			Condition	
Species	Adult M/F	Nymph	Larva	flat	part	full	alive	dead☀
Amblyomma americanum lone star tick								
Dermacentor variabilis American dog tick								
Ixodes scapularis blacklegged tick (a.k.a. deer tick)								
Other:								

THIS TICK WAS TESTED FOR:	Pos	Neg*
Anaplasma phagocytophilum (human granulocytic ehrlichiosis, HGE)		
Babesia microti (babesiosis)		
Borrelia burgdorferi (Lyme disease, LD)		
Borrelia lonestari (southern tick-associated rash illness, STARI)		
Ehrlichia chaffeensis (human monocytic ehrlichiosis, HME)		
Rickettsia rickettsii (Rocky Mountain spotted fever)		

<sup>\*</sup> Tests performed on live ticks are the most accurate. Negative test results for dead ticks can be unreliable (i.e., they may be False Negative), because the DNA of pathogenic organisms begins to degrade once the tick dies. Therefore, the patient should be alert for symptoms of tick-borne diseases appearing 1 to 4 weeks following the tick bite.
